

Report

Hypatia - LEO satellite network simulation framework

Introduction

Hypatia is a simulation framework designed for satellite network research. This report summarizes the system setup, installation, and testing procedures based on the provided documentation.

System Requirements

To ensure proper functionality, the following system requirements must be met:

- **Python Version:** 3.7 or later
- **Operating System:** A recent Linux distribution (e.g., Ubuntu 18+)

In our project, we tried with this system set-up but it gave a lot of bugs, specially with Python 3.12.7 So we downgrade the version to 3.11, then to 3.8.20 then to 3.7. For the OS, we worked directly on WSL. We have found a very efficient way to install, build and run the dependencies which is: Google T4 Server provided by Google Colab Platform.

Installation Steps

0. Copy Hypatia repo from github to colab:

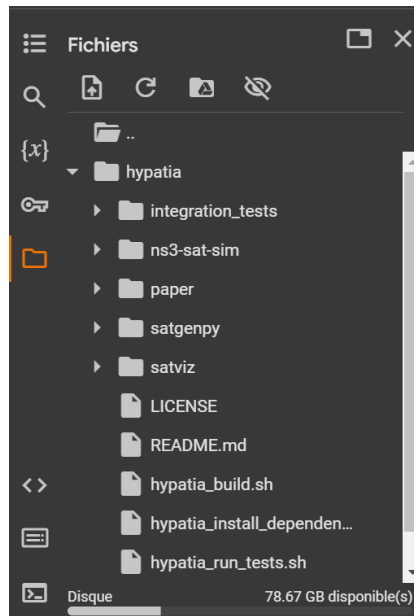

Before start working on Google T4 Server, we need the hypatia repository deployed on github to be on colab, we lunch the following command to copy the remote repository to our local machine (T4 Server) :

git clone <https://github.com/snkas/hypatia.git>

```
[ ] !git clone https://github.com/snkas/hypatia.git

Cloning into 'hypatia'...
remote: Enumerating objects: 1177, done.
remote: Counting objects: 100% (660/660), done.
remote: Compressing objects: 100% (179/179), done.
remote: Total 1177 (delta 510), reused 481 (delta 481), pack-reused 517 (from 1)
Receiving objects: 100% (1177/1177), 33.47 MiB | 14.28 MiB/s, done.
Resolving deltas: 100% (743/743), done.
```

Now, we see that the hypatia repository is disponible on our colab workspace.

1. Install Dependencies

Before running Hypatia, dependencies need to be installed. This was done using the following command:

```
bash hypatia_install_dependencies.sh
```

```
[ ] !cd hypatia && bash hypatia_install_dependencies.sh

Preparing metadata (setup.py) ... done
Building wheels for collected packages: networkload
Building wheel for networkload (setup.py) ... done
Created wheel for networkload: filename=networkload-1.3-py3-none-any.whl
Stored in directory: /tmp/pip-ephem-wheel-cache-16hq53gq/wheels/22/84/
Successfully built networkload
Installing collected packages: networkload
Successfully installed networkload-1.3
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
gnuplot is already the newest version (5.4.2+dfsg2-2).
0 upgraded, 0 newly installed, 0 to remove and 25 not upgraded.

Hypatia dependencies have been installed.
```

This script will automatically download and install the necessary packages required for Hypatia to function correctly.

2. Build Modules

Hypatia consists of multiple modules that need to be built. The following command attempts to build all modules:

bash hypatia_build.sh

After running the command ``bash hypatia_build.sh``, we encountered numerous unexpected bugs and errors. We resolved the issue by replacing the ``basic-simulation.cc`` file, as the original version contained coding errors that we fixed.

```
[ ] !cp /content/basic-simulation.cc /content/hypatia/ns3-sat-sim/simulator/contrib/basic-sim/model/core/basic-simulation.cc
```

After 43 minutes of building, the script arrived finally to build most of the hypatia modules.

```
[ ] !cd hypatia && bash hypatia_build.sh

'build' finished successfully (42m54.614s)

Modules built:
antenna                aodv                    applications
basic-sim (no Python)  bridge                  buildings
config-store           core                    csma
csma-layout            dsdv                    dsr
energy                 fd-net-device           flow-monitor
internet               internet-apps           lr-wpan
lte                    mesh                    mobility
mpi                    netanim                 network
nix-vector-routing     olsr                    point-to-point
point-to-point-layout  propagation             satellite (no Python)
satellite-network (no Python) sixlowpan                spectrum
stats                  tap-bridge              test (no Python)
topology-read          traffic-control          uan
virtual-net-device     wave                    wifi
wimax

Modules not built (see ns-3 tutorial for explanation):
brite                  click                   openflow
visualizer

Nothing to build for satgenpy.
Nothing to build for satviz.
Nothing to build for paper.

Hypatia modules have been built.
```

3. Run Tests

To verify that Hypatia is correctly installed and functioning, we run the test suite using:

bash hypatia_run_tests.sh

The first time we launched this command; it was blocked after one hour of running those tests so it didn't work for the first or second time because there were many bugs on the original files of hypatia. After extensive interpretation and analysis, we replaced all the necessary files - after fixing all bugs and errors - and executed the following commands:

```
[ ] !cp /content/top.html /content/hypatia/satviz/static_html/top.html

[ ] !cp /content/visualize_constellation.py /content/hypatia/satviz/scripts/visualize_constellation.py

[ ] !pip install dms2dec

[ ] !apt-get install screen
```

After that, we launch the run command which ensures that all modules and dependencies are correctly set up and that the system operates as expected - it takes about 38 minutes to run all the tests and make all the plots.

```
[ ] lcd hypatia && bash hypatia_run_tests.sh

Verification completed
Nothing to test for paper.

Hypatia tests were run and passed.
```

Paper Reproduction

By following the given paper documentation. It's evident that some components of Hypatia require extensive computational time. In order to expedite the process, we download pre-generated data from the github repository then we upload it to colab.

```
[4] !mv /content/hypatia_paper_temp_data.tar.gz /content/hypatia/paper
```

To proceed, we ensure the following Python packages are installed: numpy, exputil and networkload

```
[5] !pip install numpy
!pip install git+https://github.com/snkas/exputilpy.git@v1.6
!pip install git+https://github.com/snkas/networkload.git@v1.3

Requirement already satisfied: numpy in /usr/local/lib/python3.11/dist-packages (1.26.4)
Collecting git+https://github.com/snkas/exputilpy.git@v1.6

Successfully built networkload
Installing collected packages: networkload
Successfully installed networkload-1.3
```

We install gnuplot by the following command:

sudo apt-get install gnuplot

Then, we extract temp data from the `hypatia_paper_temp_data.tar.gz`

```
[7] !cd hypatia/paper/ && python extract_temp_data.py

> Deleting.... figures/a_b/tcp_cwnd/pdf
> Creating.... figures/a_b/tcp_cwnd/pdf
> Extracting.... figures/a_b/tcp_cwnd/pdf
> Deleting.... figures/a_b/tcp_isls_vs_gs_relays/pdf
> Creating.... figures/a_b/tcp_isls_vs_gs_relays/pdf
> Extracting.... figures/a_b/tcp_isls_vs_gs_relays/pdf

> Deleting.... ns3_experiments/traffic_matrix_load/pdf
> Creating.... ns3_experiments/traffic_matrix_load/pdf
> Extracting.... ns3_experiments/traffic_matrix_load/pdf

Removing temporary temp_data/ directory which was used for extraction
Finished.
```

Step 1: generating LEO satellite network dynamic state over time

In order to generate the satellite network state. We need the *satgenpy* or *satgen* Python module, which are located at the root of Hypatia. For each satellite network defined in here (Kuiper-630, Starlink-550, Telesat-1015), it generates for a ranging set of scenarios the following static state:

- List of satellites which are encoded using TLEs (*tles.txt*)
- List of ISLs (*isls.txt*)

- List of ground stations (*ground_stations.txt*)
- Description of the maximum GSL and ISL length in meters (*description.txt*)
- Number of GSL interfaces each node (satellite and ground station) has, and their total bandwidth sum (*gsl_interfaces_info.txt*)

Before launching the command: **bash generate_all_local.sh**, we checked that all hypatia dependencies were successfully installed (including *satgenpy* modules which are essential for generating satellite network states).

```

```

```
|-- telesat_1015_isls_plus_grid_ground_stations_top_100_algorithm_free_one_only_over_isls
```

Step 2: build ns-3 simulator

Here we install all ns-3 dependencies (inherited from basic-sim ns-3 module) using these commands:

```
sudo apt-get update
```

```
sudo apt-get -y install openmpi-bin openmpi-common openmpi-doc libopenmpi-dev lcov gnuplot
```

```
pip install numpy statsmodels
```

```
pip install git+https://github.com/snkas/exputilpy.git@v1.6
```

```
git submodule update --init --recursive
```

Then, we launch the optimized build using: **bash build.sh --optimized**, we obtain:

```
!cd hypatia/ns3-sat-sim && bash build.sh --optimized
[2897/2897] Linking build/debug_all/src/tap-bridge/ns3.31-tap-creator-debug
Waf: Leaving directory `/content/hypatia/ns3-sat-sim/simulator/build/debug_all
Build commands will be stored in build/debug_all/compile_commands.json
'build' finished successfully (42m54.614s)

Modules built:
antenna                aodv                    applications
basic-sim (no Python)  bridge                 buildings
config-store           core                    csma
csma-layout            dsdv                    dsr
energy                 fd-net-device          flow-monitor
internet               internet-apps          lr-wpan
lte                     mesh                    mobility
mpi                     netanim                network
nix-vector-routing     olsr                    point-to-point
point-to-point-layout  propagation            satellite (no Python)
satellite-network (no Python) sixlowpan              spectrum
stats                  tap-bridge             test (no Python)
topology-read          traffic-control         uan
virtual-net-device     wave                    wifi
wimax

Modules not built (see ns-3 tutorial for explanation):
brite                  click                   openflow
visualizer

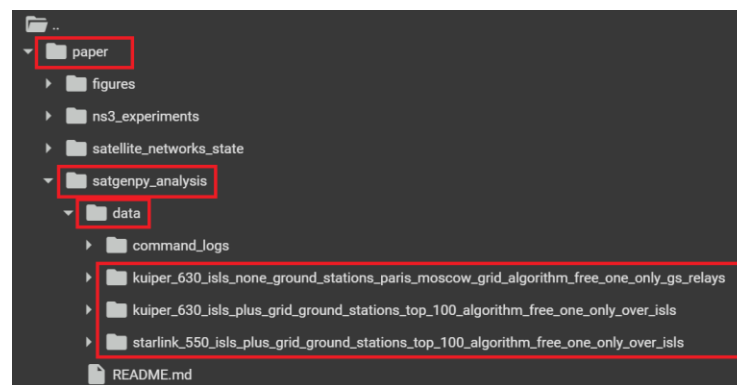

Nothing to build for satgenpy.
Nothing to build for satviz.
Nothing to build for paper.

Hypatia modules have been built.
```

Step 3: performing analysis using satgenpy

Till now we have the generated satellite network state data over time in `satellite_networks_state`, here we can launch an analysis of the constellations, for both as a whole, as well as for a few particular pairs. So before perform the full analysis, we shall check that all *satgenpy* dependencies were installed then we launch the command: **python perform_full_analysis.py**

The analysis for each constellation is now in `data/<satellite network name>`

Here some screenshots from the PDF file generated for kuiper satellite:

Step 4: running ns-3 experiments

Working on it

Conclusion

Setting up Hypatia requires a Linux environment with Python 3.7+, installation of dependencies, module compilation, and testing. The documentation provides a structured approach to ensure a smooth setup and usage experience. Users are encouraged to refer to the tutorial located in the [paper/README.md](#) file for in-depth guidance on using Hypatia effectively.
